

## DFA - Exercise

*Problem:*

Construct a DFA for  $L = \{ab^n a^m : n \geq 2, m \geq 3\}$ .

*Solution:*

We start by analyzing the type of strings accepted by this language. The string must start with an 'a'. This is followed by 2 or more 'b's. It is ended with three or more 'a's. Example strings include *abbaaa*, *abbbbaaa*, and *abbbbbbbbaaaaa*. The string *abb* is not in the language because there is no trailing a's. Similarly with *aaaa*, it is not accepted because there has to be two or more b's in the middle of the string.

We start building the DFA with an initial state and a second state remembering that the first *a* is read. Note that we will focus on the strings to be accepted by the DFA. We will add a trap state to take care of all rejected strings at the end.

We build on this by adding two more states to remember the fact that two *b*'s have been read.

Next, we add a loop back on the last state to any number of *b*'s after the first two *b*'s.

As we did with processing the two *b*'s, we will now add three more states to remember three consecutive *a*'s read after the *b*'s.

We add a loop back on the last state to accept any string of trailing *a*'s after the three *a*'s.

Next, we make the last state the final state to signify acceptance of the string.

Finally, we add a reject state to send input sequences that are not in the language.

Test the DFA with sample strings.
