

## DFA Minimization

Minimize the following DFA

The DFA minimization is done by clicking the convert menu and then the minimize DFA option.

The algorithm being used is one of partitioning, due to Hopcroft. First the states are split into final and non-final states as shown here

Now to partition the states further we repeatedly choose a set A from the current partition and an input symbol c, and split each of the sets of the partition into two (possibly empty) subsets: the subset of states that lead to A on input symbol c, and the subset of states that do not lead to A.

For instance since  $\{0, 1, 2, 4\}$  on an input of 0 goes to 2, 4, 2, 2 respectively and all of those are in the set, there is no splitting based on the 0 input. However, on an input of 1 we notice these states going to 1, 3, 1, 1 respectively. So state  $q_1$  is not equivalent to states  $q_0, q_2, q_4$ .

For the states  $q_3, q_5, q_6$  it is easy to see that they are all interconnected and therefore will not be split up by this partitioning procedure. So at the end of the day you have 3 equivalence classes  $\{q_0, q_2, q_4\}, \{q_1\}$  and  $\{q_3, q_5, q_6\}$  as seen here

Once the states have been partitioned into equivalence classes, the minimized DFA is produced as follows.
